Develop a workflow pattern for taking the finished technical manuals i have developed, convert them into a teaching script that includes slide descriptions for the image gen to create, add an AI voice to read it, and a series of slides. Have a script that orders the slides, intro graphic, outro and transitions between them and then automatically generates the video, as well as makes the audio track. Uses a professional video creation tool for professional transitions and effects. Probably needs a sound board for things like new slides appearing, "a shutter sound" when photos are displayed, etc. New slides should have a camera effect associated with them (pan, zoom, fade, etc), like documentaries are made (research what the techniques are used to create a documentary video from still shots is, and a method to implement said animations) I have access to any software I need, price is no issue, although pay-per-service online payment models are discouraged (i think i can figure out a free alternative), so always pick the BEST tool for the job. This will essentially be a synthesis of two existing project flows, the documentary flow described above, and a slide based presentation style (see techniques effectively used at tech security, graphic design and other technology companies for their presentations as these are the A-tier options. Include other A-tier methods if I have missed them and research them as well). Final output will be a collection of documents for implementing this idea:

```
-Executive summary (for distribution to collaborators and potential funders)
-Technical analysis of methods used to produce still image based documentaries.
-Technical analysis of methods used by A-tier presentations for the absolute most effective way to disseminate the information and retain / gain viewers.
-project brief for roo-code or gemini terminal to generate the code needed for production of the visual portion of the project.
-Project brief for roo-code or gemini terminal to generate the code needed for production of the audio portion of the project.
-Project brief for roo-code or gemini terminal to generate the code needed for production of the final integration portion of the project, as well as post production, A/B thumbnail and title generation (AI assisted).
-An objects report on the needed tools and data to produce this project at scale (software, data, etc.).
-An instruction document on the best methods for obtaining the images needed by the script (all AI generated, this is a prompting guide for the various types of images we will be using (types should be defined in the documentary technical analysis document)
-An instruction document on the best methods for obtaining the slides needed by the script (all AI generated, this is a prompting guide for the various types of slides we will be using. These will be created via a combination of html, and AI image gen (this offers the best stylistic freedom, allows for absolute control over written elements and incorporates high-res generated images to retain interest) (types should be defined in the presentation technical analysis document)
-An instruction document on the best methods for obtaining the sound effects needed by the script (all AI generated, this is a prompting guide for the various types of audio enhancements we will be using (types should be defined in the documentary and presentation technical analysis documents)
-A "secrets" document, outlining the user specific data requirements to produce this project at scale (this will be created after the above documents are done as the output of the above are needed to complete this task)
```

All of the above documents will be generated via deep analysis on the various AI portals and then the best selected. Unselected output will be stored for post production project analysis report (which tools worked best, what did not work, what can be done to improve the process further). Through iterative refinement of all the produced elements this project will aim to turn 10-20 page documentation on various tasks completed by the user into a fully automated video generation pipeline.

What didn't I think of for this project? Do the preliminary research needed for the generation of a system prompt to be provided to the deep analysis tool for each of the output products defined above. Make sure to define the project context in each prompt; the goal is production quality output for all of our .. I know there is a cool word for those papers..vitals? what am i thinking of here?

Additionally consider the order of operations for conducting the research. For instance the secrets document cannot be completed until all the other papers are done. What other items have prerequisites provided by the other tasks? Produce an operations chain containing the order in which the deep analysis prompts should be submitted, and which tasks can be run concurrently. Additionally identify these prerequisites and include the production of their definitions in the respective prompts so that the data can be easily appended to the appropriate location within the other prompts.
